$\mathsf{Basic}\ \mathsf{C}\text{++}\ \mathsf{Syntax}$

Overview

Common set of basic features shared by a wide range of programming languages

- Built-in types (integers, characters, floating point numbers, etc.)
- Variables ("names" for entities)
- Expressions and statements to manipulate values of variables
- Control-flow constructs (if, for, etc.)
- Functions, i.e. units of computation

Supplemented by additional functionality

- Programmer-defined types (struct, class, etc.)
- Library functions

The C++ Reference Documentation

 $C{\leftrightarrow\!\!\!+}$ is in essence a simple language

- Limited number of basic features and rules
- But: There is a corner case to most features and an exception to most rules
- But: Some features and rules are rather obscure

These slides will necessarily be inaccurate or incomplete at times

- https://en.cppreference.com/w/cpp provides an excellent and complete reference documentation of C++
- Every C++ programmer should be able to read and understand the reference documentation
- Slides that directly relate to the reference documentation contain the
 Symbol with a link to the relevant webpage in the slide header

Look at these links and familiarize yourself with the reference documentation!

Comments

 $C +\!\!\!+$ supports two types of comments

- "C-style" or "multi-line" comments: /* comment */
- "C++-style" or "single-line" comments: // comment

Example

```
/* This comment is unnecessarily
   split over two lines */
int a = 42;
// This comment is also split
// over two lines
int b = 123;
```

Fundamental Types

C++ defines a set of primitive types

- Void type
- Boolean type
- Integer types
- Character types
- Floating point types

All other types are composed of these fundamental types in some way

Void Type

The void type has no values

- Identified by the C++ keyword void
- No objects of type void are allowed
- Mainly used as a return type for functions that do not return any value
- Pointers to void are also permitted

Boolean Type

The boolean type can hold two values

- Identified by the C++ keyword bool
- Represents the truth values true and false
- Quite frequently obtained from implicit automatic type conversion

Integer Types (1)

The integer types represent integral values

- Identified by the C++ keyword int
- Some properties of integer types can be changed through modifiers
- int keyword may be omitted if at least one modifier is used

Signedness modifiers

- signed integers will have signed representation (i.e. they can represent negative numbers)
- Since C++20 signed integers must use two's complement representation
- unsigned integers will have unsigned representation (i.e. they can only represent non-negative numbers)

Size modifiers

- short integers will be optimized for space (at least 16 bits wide)
- long integers will be at least 32 bits wide
- long long integers will be at least 64 bits wide

Integer Types (2)

Modifiers and the int keyword can be specified in any order

```
// a, b, c and d all have the same type
unsigned long long int a;
unsigned long long b;
long unsigned int long c;
long long unsigned d;
```

By default integers are signed, thus the signed keyword can be omitted

```
// e and f have the same type
signed int e;
int f;
```

By convention modifiers are ordered as follows

- 1. Signedness modifier
- 2. Size modifier
- 3. (int)

Integer Type Overview

Overview of the integer types as specified by the C++ standard

Canonical Type Specifier	Minimum Width	Minimum Range
short unsigned short	16 bit	-2^{15} to $2^{15} - 1$ 0 to $2^{16} - 1$
int unsigned	16 bit	-2^{15} to $2^{15}-1$ 0 to $2^{16}-1$
long unsigned long	32 bit	-2^{31} to $2^{31} - 1$ 0 to $2^{32} - 1$
long long unsigned long long	64 bit	-2^{63} to $2^{63}-1$ 0 to $2^{64}-1$

The exact width of integer types is **not** specified by the standard!

Fixed-Width Integer Types

Sometimes we need integer types with a guaranteed width

- Use fixed-width integer types defined in <cstdint> header
- int8_t, int16_t, int32_t and int64_t for signed integers of width 8, 16, 32 or 64 bit, respectively
- uint8_t, uint16_t, uint32_t and uint64_t for unsigned integers of width 8, 16, 32 or 64 bit, respectively

Only defined if the C^{++} implementation directly supports the type

```
#include <cstdint>
long a; // may be 32 or 64 bits wide
int32_t b; // guaranteed to be 32 bits wide
int64_t c; // guaranteed to be 64 bits wide
```

Integer Type Guidelines

Use basic (i.e. non-fixed-width) integer types by default

- They guarantee a minimum range that can be supported
- Most of the time we do not need to know an exact maximum value
- Usually (unsigned) int or long are a reasonable choice

Only use fixed-width integer types where absolutely required

- E.g. in data structures that need to have deterministic fixed size
- E.g. in library calls
- E.g. for bitwise operations that rely on masks, shifts etc.

Do not prematurely optimize for space consumption

- Registers on modern CPUs are likely to be 64 bit wide anyway
- Most of the time a program only becomes susceptible to overflow bugs if narrow integer types are used without good reason

Character Types

Character types represent character codes and (to some extent) integral values

- Identified by C++ keywords signed char and unsigned char
- Minimum width is 8 bit, large enough to represent UTF-8 eight-bit code units
- The C++ type char may either be equivalent to signed char or unsigned char, depending on the implementation
- Nevertheless char is always a distinct type
- signed char and unsigned char are sometimes used to represent small integral values

Larger UTF characters are supported as well

- char16_t for UTF-16 character representation
- char32_t for UTF-32 character representation

Floating Point Types

Floating point types of varying precision

- float usually represents IEEE-754 32 bit floating point numbers
- double usually represents IEEE-754 64 bit floating point numbers
- long double is a floating point type with extended precision (varying width depending on platform and OS, usually between 64 bit and 128 bit)

Floating point types may support special values

- Infinity
- Negative zero
- Not-a-number

Implicit Conversions (1)

Type conversions may happen automatically

- If we use an object of type A where an object of type B is expected
- Exact conversion rules are highly complex (full details in the reference documentation)

Some common examples

- If one assigns an integral type to bool the result is false if the integral value is 0 and true otherwise
- If one assigns bool to an integral type the result is 1 if the value is true and
 o otherwise
- If one assigns a floating point type to an integral type the value is truncated
- If one assigns an out-of-range value to an unsigned integral type of width w, the result is the original value modulo 2^w

Implicit Conversions (2)

Example

```
uint16_t i = 257;
uint8_t j = i; // j is 1
if (j) {
    /* executed if j is not zero */
}
```

Undefined Behavior (1)

In some situations the behavior of a program is not well-defined

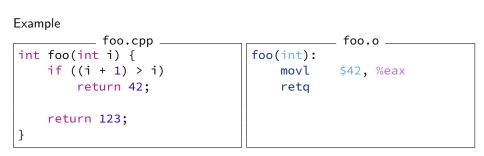

- E.g. overflow of an unsigned integer is well-defined (see previous slide)
- But: Signed integer overflow results in undefined behavior
- We will encounter undefined behavior every once in a while

Undefined behavior falls outside the specification of the C++ standard

- The compiler is allowed to do anything when it encounters undefined behavior
- Fall back to some sensible default behavior
- Do nothing
- Print 42
- Do anything else you can think of

A C++ program must never contain undefined behavior!

Undefined Behavior (2)

Undefined Behavior (3)

Undefined behavior differs from unspecified or implementation-defined behavior

- Unspecified or implementation-defined behavior is still valid C++
- However its effects may be different across compilers
- Only implementation-defined behavior is required to be documented

Undefined behavior gives compilers more freedom for optimization

- They can assume that programs contain no undefined behavior
- E.g. makes it possible for the compiler to omit some checks

Example

- Out-of-bounds array accesses are undefined behavior
- Therefore, the compiler does not need to generate range checks for each array access

Variables

Variables need to be defined before they can be used

- Simple declaration: Type specifier followed by comma-separated list of declarators (variable names) followed by semicolon
- Variable names in a simple declaration may optionally be followed by an initializer

```
void foo() {
    unsigned i = 0, j;
    unsigned meaningOfLife = 42;
}
```

Variable Initializers (1)

Initialization provides an initial value at the time of object construction

- 1. variableName(<expression>)
- 2. variableName = <expression>
- 3. variableName{<expression>}

Important differences

- Options 1 and 2 simply assign the value of the expression to the variable, possibly invoking implicit type conversions
- Option 3 results in a compile error if implicit type conversions potentially result in loss of information
- A declaration may contain no initializer
 - Non-local variables are default-initialized (to zero for built-in types)
 - Local variables are usually **not** default-initialized

Accessing an uninitialized variable is undefined behavior

Variable Initializers (2)

double a = 3.1415926;		
double b(42);		
unsigned c = a;	// OK: c == 3	
unsigned d(b);	// OK: d == 42	
<pre>unsigned e{a};</pre>	<pre>// ERROR: potential information loss</pre>	
unsigned f{b};	<pre>// ERROR: potential information loss</pre>	

Initializers may be arbitrarily complex expressions

double pi = 3.1415926, z = 0.30, a = 0.5; double volume(pi * z * z * a);

Integer Literals

Integer literals represent constant values embedded in the source code

- Decimal: 42
- Octal: 052
- Hexadecimal: 0x2a
- Binary: 0b101010

The following suffixes may be appended to a literal to specify its type

- unsigned suffix: 42u or 42U
- Long suffixes:
 - Iong suffix: 421 or 42L
 - Iong long suffix: 42ll or 42LL
- Both suffixes can be combined, e.g. 42ul, 42ull

Single quotes may be inserted between digits as a separator

- e.g. 1'000'000'000'000ull
- e.g. 0b0010'1010

Floating-point literals

C

Floating-point literals represent constant values embedded in the source code

- Without exponent: 3.1415926, .5
- With exponent: 1e9, 3.2e20, .5e-6

One of the following suffixes may be appended to a literal to specify its type

- float suffix: 1.0f or 1.0F
- long double suffix: 1.0l or 1.0L

Single quotes may be inserted between digits as a separator

- e.g. 1'000.000'001
- e.g. .141'592e12

Character Literals

Character literals represent constant values embedded in the source code

- Any character from the source character set except single quote, backslash and newline, e.g. 'a', 'b', '€'
- Escape sequences, e.g. '\'', '\\', '\n', '\u1234'

One of the following prefixes may be prepended to a literal to specify its type

- UTF-8 prefix: u8'a', u8'b'
- UTF-16 prefix: u'a', u'b'
- UTF-32 prefix: U'a', U'b'

Const & Volatile Qualifiers (1)

Any type T in C++ (except function and reference types) can be *cv-qualified*

- const-qualified: const T
- volatile-qualified: volatile T
- cv-qualifiers can appear in any order, before or after the type

Semantics

- const objects cannot be modified
- Any read or write access to a volatile object is treated as a visible side effect for the purposes of optimization
- volatile should be avoided in most cases (it is likely to be deprecated in future versions of C++)
- Use *atomics* instead

Const & Volatile Qualifiers (2)

Only code that contributes to observable side-effects is emitted

```
int main() {
    int a = 1; // will be optimized out
    int b = 2; // will be optimized out
    volatile int c = 42;
    volatile int d = c + b;
}
```

Possible x86-64 assembly (compiled with -01)

main:

```
movl $42, -4(%rsp) # volatile int c = 42
movl -4(%rsp), %eax # volatile int d = c + b;
addl $2, %eax # volatile int d = c + b;
movl %eax, -8(%rsp) # volatile int d = c + b;
movl $0, %eax # implicit return 0;
ret
```

Expression Fundamentals

 $C{\leftrightarrow\!\!\!+}$ provides a rich set of operators

- Operators and operands can be composed into expressions
- Most operators can be overloaded for custom types

Fundamental expressions

- Variable names
- Literals

Operators act on a number of operands

- Unary operators: E.g. negation (-), address-of (&), dereference (*)
- Binary operators: E.g. equality (==), multiplication (*)
- Ternary operator: a ? b : c

Value Categories

Each expression in C++ is characterized by two independent properties

- Its type (e.g. unsigned, float)
- Its value category
- Operators may require operands of certain value categories
- Operators result in expressions of certain value categories

Broadly (and inaccurately) there are two value categories: Ivalues and rvalues

- lvalues refer to the identity of an object
- rvalues refer to the value of an object
- Modifiable lvalues can appear on the left-hand side of an assignment
- Ivalues and rvalues can appear on the right-hand side of an assignment

C++ actually has a much more sophisticated taxonomy of expressions

• Will (to some extent) become relevant later during the course

Arithmetic Operators (1)

Operator	Explanation
+a	Unary plus
-a	Unary minus
a + b	Addition
a - b	Subtraction
a * b	Multiplication
a / b	Division
a % b	Modulo
~a	Bitwise NOT
a & b	Bitwise AND
a b	Bitwise OR
a ^ b	Bitwise XOR
a << b	Bitwise left shift
a >> b	Bitwise right shift

 $C\!\!+\!\!+$ arithmetic operators have the usual semantics

Arithmetic Operators (2)

Incorrectly using the arithmetic operators can lead to undefined behavior, e.g.

- Signed overflow (see above)
- Division by zero
- Shift by a negative offset
- Shift by an offset larger than the width of the type

Logical and Relational Operators (1)

Operator	Explanation
!a a && b	Logical NOT Logical AND (short-circuiting)
a b	Logical OR (short-circuiting)
a == b	Equal to
a != b	Not equal to
a < b	Less than
a > b	Greater than
a <= b	Less than or equal to
a >= b	Greater than or equal to
a <=> b	Three-way comparison

Most C++ logical and relational operators have the usual semantics

Logical and Relational Operators (2)

The three-way comparison (or spaceship) operator is a useful addition in C++20

- (a <=> b) < 0 if a < b
- (a <=> b) == 0 if a == b
- (a <=> b) > 0 if a > b
- Can be generated by the compiler automatically in some cases
- Facilitates, for example, sorting values

Assignment Operators (1)

C
-

Operator	Explanation
a = b	Simple assignment
a += b	Addition assignment
a -= b	Subtraction assignment
a *= b	Multiplication assignment
a /= b	Division assignment
a %= b	Modulo assignment
a &= b	Bitwise AND assignment
a = b	Bitwise OR assignment
a ^= b	Bitwise XOR assignment
a <<= b	Bitwise left shift assignment
a >>= b	Bitwise right shift assignment

Notes

- The left-hand side of an assignment operator must be a modifiable lvalue
- For built-in types a OP= b is equivalent to a = a OP b except that a is only evaluated once

Assignment Operators (2)

The assignment operators return a reference to the left-hand side

```
unsigned a, b, c;
a = b = c = 42; // a, b, and c have value 42
```

Usually rarely used, with one exception

```
unsigned d;
if (d = computeValue()) {
    // executed if d is not zero
} else {
    // executed if d is zero
}
// unconditionally do something with d
```

Increment and Decrement Operators

Operator	Explanation
++a	Prefix increment
a	Prefix decrement
a++	Postfix increment
a	Postfix decrement

Return value differs between prefix and postfix variants

- Prefix variants increment or decrement the value of an object and return a *reference* to the result
- Postfix variants create a copy of an object, increment or decrement the value of the original object, and return the copy

Ternary Conditional Operator

Operator	Explanation
a ? b : c	Conditional operator

Semantics

- a is evaluated and converted to bool
- If the result was true, b is evaluated
- Otherwise c is evaluated

The type and value category of the resulting expression depend on the operands

int n = (1 > 2)? 21 : 42; // 1 > 2 is false, i.e. n == 42int m = 42; ((n == m) ? m : n) = 21; // n == m is true, i.e. m == 21 int k{(n == m) ? 5.0 : 21}; // ERROR: narrowing conversion ((n == m) ? 5 : n) = 21; // ERROR: assigning to rvalue

Precedence and Associativity (1)

How to group multiple operators in one expression?

- Operators with higher precedence bind tighter than operators with lower precedence
- Operators with equal precedence are bound in the direction of their associativity
 - Ieft-to-right
 - right-to-left
- Often grouping is not immediately obvious: Use parentheses judiciously!

Precedence and associativity do not specify evaluation order

- Evaluation order is mostly unspecified
- Generally, it is undefined behavior to refer to and change the same object within one expression

Precedence and Associativity (2)

In some situations grouping is obvious

int a = 1 + 2 * 3; // 1 + (2 * 3), i.e. a == 7

However, things can get confusing really quickly

int b = 50 - 6 - 2; // (50 - 6) - 2, i.e. b == 42int c = b & 1 << 4 - 1; // b & (1 << (4 - 1)), i.e. c == 8// real-world examples from libdcraw diff = ((getbits(len-shl) << 1) + 1) << shl >> 1; // ??? yuv[c] = (bitbuf >> c * 12 & 0xfff) - (c >> 1 << 11); // ???</pre>

Bugs like to hide in expressions without parentheses

// shift should be 4 if sizeof(long) == 4, 6 otherwise unsigned shift = 2 + sizeof(long) == 4 ? 2 : 4; // buggy

Expressions

Operator Precedence Table (1)

Prec.	Operator	Description	Associativity
1	::	Scope resolution	left-to-right
	a++ a	Postfix increment/decrement	
	<type>()</type>	Functional Cast	
2	<type>{}</type>		left-to-right
	a()	Function Call	
	a[]	Subscript	
	>	Member Access	
	++aa	Prefix increment/decrement	
	+a -a	Unary plus/minus	
	! ~	Logical/Bitwise NOT	
	(<type>)</type>	C-style cast	
3	*a	Dereference	right-to-left
	&a	Address-of	
	sizeof	Size-of	
	new new[]	Dynamic memory allocation	
	delete delete[]	Dynamic memory deallocation	

Expressions

Operator Precedence Table (2)

Prec.	Operator	Description	Associativity
4	.* ->*	Pointer-to-member	left-to-right
5	a*b a/b a%b	Multiplication/Division/Remain- der	left-to-right
6	a+b a-b	Addition/Subtraction	left-to-right
7	<< >>	Bitwise shift	left-to-right
8	<=>	Three-way comparison	left-to-right
9	< <= > >=	Relational $<$ and \leq Relational $>$ and \geq	left-to-right
10	== !=	$Relational = and \neq$	left-to-right

Expressions

Operator Precedence Table (3)

Prec.	Operator	Description	Associativity
11	&	Bitwise AND	left-to-right
12	٨	Bitwise XOR	left-to-right
13		Bitwise OR	left-to-right
14	&&	Logical AND	left-to-right
15		Logical OR	left-to-right
16	a?b:c throw = += -= *= /= %= <<= >>= &= ^= =	Ternary conditional throw operator Direct assignment Compound assignment Compound assignment Compound assignment Compound assignment	right-to-left
17	,	Comma	left-to-right

Simple Statements

Declaration statement: Declaration followed by a semicolon

int i = 0;

Expression statement: Any expression followed by a semicolon

i + 5; // valid, but rather useless expression statement
foo(); // valid and possibly useful expression statement

Compound statement (blocks): Brace-enclosed sequence of statements

{	// start of block
int i = 0;	<pre>// declaration statement</pre>
}	<pre>// end of block, i goes out of scope</pre>
int i = 1;	<pre>// declaration statement</pre>

Scope

Names in a C++ program are valid only within their scope

- The scope of a name begins at its point of declaration
- The scope of a name ends at the end of the relevant block
- Scopes may be shadowed resulting in discontiguous scopes (bad practice)

```
int a = 21;
int b = 0;
{
   int a = 1; // scope of the first a is interrupted
   int c = 2;
   b = a + c + 39; // a refers to the second a, b == 42
                    // scope of the second a and c ends
  = a;
                    // a refers to the first a, b == 21
 += c:
                    // ERROR: c is not in scope
```

If Statement (1)

Conditionally executes another statement

```
if (init-statement; condition)
    then-statement
else
    else-statement
```

Explanation

- If *condition* evaluates to true after conversion to bool, *then-statement* is executed, otherwise *else-statement* is executed
- Both init-statement and the else branch can be omitted
- If present, init-statement must be an expression or declaration statement
- condition must be an expression statement or a single declaration
- then-statement and else-statement can be arbitrary (compound) statements

If Statement (2)

The init-statement form is useful for local variables only needed inside the if

```
if (unsigned value = computeValue(); value < 42) {
    // do something
} else {
    // do something else
}</pre>
```

Equivalent formulation

```
{
    unsigned value = computeValue();
    if (value < 42) {
        // do something
    } else {
        // do something else
    }
}</pre>
```

Statements

If Statement (3)

In nested if-statements, the else is associated with the closest if that does not have an else

```
INTENTIONALLY BUGGY!
if (condition0)
    if (condition1)
        // do something if (condition0 && condition1) == true
else
    // do something if condition0 == false
```

When in doubt, use curly braces to make scopes explicit

```
// Working as intended
if (condition0) {
    if (condition1)
    // do something if (condition0 && condition1) == true
} else {
    // do something if condition0 == false
```

Statements

Switch Statement (1)

Conditionally transfer control to one of several statements

switch (init-statement; condition) statement

Explanation

- condition may be an expression or single declaration that is convertible to an enumeration or integral type
- The body of a switch statement may contain an arbitrary number of case constant: labels and up to one default: label
- The constant values for all case: labels must be unique
- If condition evaluates to a value for which a case: label is present, control is passed to the labelled statement
- Otherwise, control is passed to the statement labelled with default:
- The break; statement can be used to exit the switch

Switch Statement (2)

Regular example

```
switch (computeValue()) {
   case 21:
      // do something if computeValue() was 21
      break;
   case 42:
      // do something if computeValue() was 42
      break;
   default:
      // do something if computeValue() was != 21 and != 42
      break;
}
```

Switch Statement (3)

The body is executed sequentially until a break; statement is encountered

```
switch (computeValue()) {
    case 21:
    case 42:
        // do something if computeValue() was 21 or 42
        break;
    default:
        // do something if computeValue() was != 21 and != 42
        break;
```

Compilers may generate warnings when encountering such fall-through behavior

• Use special [[fallthrough]]; statement to mark intentional fall-through

Statements

While Loop

Repeatedly executes a statement

while (condition) statement

Explanation

- Executes *statement* repeatedly until the value of *condition* becomes false. The test takes place before each iteration.
- condition may be an expression that can be converted to bool or a single declaration
- statement may be an arbitrary statement
- The break; statement may be used to exit the loop
- The continue; statement may be used to skip the remainder of the body

Do-While Loop

Repeatedly executes a statement

```
do
    statement
while (condition);
```

Explanation

- Executes statement repeatedly until the value of condition becomes false. The test takes place after each iteration.
- condition may be an expression that can be converted to bool or a single declaration
- statement may be an arbitrary statement
- The break; statement may be used to exit the loop
- The continue; statement may be used to skip the remainder of the body

While vs. Do-While

The body of a do-while loop is executed at least once

```
unsigned i = 42;
do {
    // executed once
} while (i < 42);</pre>
while (i < 42) {
    // never executed
}
```

For Loop (1)

Repeatedly executes a statement

for (init-statement; condition; iteration-expression)
 statement

Explanation

- Executes *init-statement* once, then executes *statement* and *iteration-expression* repeatedly until *condition* becomes false
- init-statement may either be an expression or declaration
- *condition* may either be an expression that can be converted to bool or a single declaration
- *iteration-expression* may be an arbitrary expression
- All three of the above statements may be omitted
- The break; statement may be used to exit the loop
- The continue; statement may be used to skip the remainder of the body

Statements

For Loop (2)

```
for (unsigned i = 0; i < 10; ++i) {</pre>
    // do something
}
for (unsigned i = 0, limit = 10; i \neq 10; i \neq 10; i \neq 10
    // do something
}
```

Beware of integral overflows (signed overflows are undefined behavior!)

```
for (uint8_t i = 0; i < 256; ++i) {</pre>
    // infinite loop
}
for (unsigned i = 42; i >= 0; --i) {
    // infinite loop
}
```

Basic Functions (1)

Functions in C++

- Associate a sequence of statements (the function body) with a name
- Functions may have zero or more function parameters
- Functions can be invoked using a function-call expression which initializes the parameters from the provided arguments

Informal function definition syntax

```
return-type name ( parameter-list ) {
    statement
}
```

Informal function call syntax

name (argument-list);

Basic Functions (2)

Function may have void return type

void procedure(unsigned parameter0, double parameter1) {
 // do something with parameter0 and parameter1

Functions with non-void return type must contain a return statement

```
unsigned meaningOfLife() {
    // extremely complex computation
    return 42;
}
```

The return statement may be omitted in the main-function of a program (in which case zero is implicitly returned)

```
int main() {
    // run the program
}
```

Basic Functions (3)

Function parameters may be unnamed, in which case they cannot be used

```
unsigned meaningOfLife(unsigned /*unused*/) {
    return 42;
}
```

An argument must still be supplied when invoking the function

```
unsigned v = meaningOfLife(); // ERROR: expected argument
unsigned w = meaningOfLife(123); // OK
```

Argument Passing

Argument to a function are passed by value in C++

```
unsigned square(unsigned v) {
    v = v * v;
    return v;
}
int main() {
    unsigned v = 8;
    unsigned w = square(v); // w == 64, v == 8
}
```

 $C{\leftrightarrow\!\!\!+}$ differs from other programming languages (e.g. Java) in this respect

- Parameters can *explicitly* be passed by reference
- Essential to keep argument-passing semantics in mind, especially when used-defined classes are involved

Default Arguments

A function definition can include default values for some of its parameters

- Indicated by including an initializer for the parameter
- After a parameter with a default value, all subsequent parameters must have default values as well
- Parameters with default values may be omitted when invoking the function

```
int foo(int a, int b = 2, int c = 3) {
   return a + b + c;
}
int main() {
   int z = foo(1, 1, 1); // z == 3
```

Function Overloading (1)

Several functions may have the same name (overloaded)

- Overloaded functions must have distinguishable parameter lists
- Calls to overloaded functions are subject to overload resolution
- Overload resolution selects which overloaded function is called based on a set of complex rules

Informally, parameter lists are distinguishable

- If they have a different number of non-defaulted parameters
- If they have at least one parameter with different type

Function Overloading (2)

Indistinguishable parameter lists (invalid C++)

```
void foo(unsigned i);
void foo(unsigned j); // parameter names do not matter
void foo(unsigned i, unsigned j = 1);
void foo(uint32_t i); // on x86_64
```

Valid example

```
void foo(unsigned i) { /* do something */ }
void foo(float f) { /* do something */ }
int main() {
   foo(lu); // calls foo(unsigned)
   foo(1.0f); // calls foo(float)
}
```

Basic IO

Basic IO (1)

Facilities for printing to and reading from the console

- Use stream objects defined in <iostream> header
- std::cout is used for printing to console
- std::cin is used for reading from console

The left-shift operator can be used to write to std::cout

```
#include <iostream>
              _____
int main() {
   unsigned i = 42;
   std::cout << "The value of i is " << i << std::endl;</pre>
}
```

Basic IO (2)

The right-shift operator can be used to read from std::cin

```
#include <iostream>
// -----
int main() {
    std::cout << "Please enter a value: " << std::flush;
    unsigned v;
    std::cin >> v;
    std::cout << "You entered " << v << std::endl;
}</pre>
```

The <iostream> header is part of the C++ standard library

- Many more interesting and useful features
- More details later
- In the meantime: Read the documentation!

Code Style

Code Formatting (1)

Projects should always use a uniform code style

- Consistent conventions for naming, documentation, etc.
- Some aspects of a uniform code style have to be implemented manually (e.g. naming conventions)

Automated code formatting can for example be performed with clang-format

- Widely available through package manager
- Highly configurable code formatting tool
- Configuration possible through .clang-format file
- Integrated in CLion

```
Code Formatting (2)
```

```
Basic clang-format usage
```

ے۔ > clang-format -i <path-to-file>

Reformats a source file in-place

- Reads formatting rules from .clang-format file in the current directory
- · Should usually reside in the source root for project-wide formatting rules
- CLion detects .clang-format files and uses them for formatting
- Can be verified by looking for "ClangFormat" in the status bar of CLion

Code Style

Code Formatting (3)

We will provide you with a .clang-format file for now

- Contains (in our opinion) sensible formatting rules
- Please make sure that your submissions are formatted according to these rules
- But our formatting rules should not be seen as the single source of truth

Some high-level formatting guidelines should be universally followed

- Descriptive names for variables and functions
- Comments for complicated sections of code
